Solar Eclipses Eye Safety

Solar eclipses result from the moon blocking sunlight, which creates a shadow on earth. Total and partial eclipses pose eye damage risks. Looking at a solar eclipse without eye protection can harm retinal cells. Damage may be permanent and painless, with delayed recognition.

Some eye symptoms that can occur from looking at a solar eclipse without proper eye protection are,

- Loss of central vision (solar retinopathy)
- Distorted vision
- Altered color vision

To safely observe a solar eclipse, prioritize your eye health. The only time it's safe to view an eclipse without special gear is during a total eclipse when the moon fully covers the sun. Avoid looking at partial eclipses without proper equipment, as even during a total eclipse, the safe viewing period is brief. Use pinhole projection as an affordable, safe alternative. Do not use smartphones or cameras without proper filters. Avoid unsafe filters like sunglasses or regular camera viewfinders, as they can damage your eyes.
