

Use the provided BST code and implement a BST that stores bank account information by numeric id. Store ID and bank balance and implement and test the following:

1. **Search for an account by ID**
 - Input an account number and display the account details (e.g., ID, balance).
2. **Deposit and Withdraw**
 - Search for a specific account by ID and update the balance.
 - If balance goes negative, optionally disallow withdrawal.
3. **Find Account with Maximum Balance**
 - Traverse the tree and find the account with the highest balance.
4. **Find Accounts Within a Balance Range**
 - Print all accounts where the balance is between two values (e.g., 10,000 to 50,000).
5. **Count High/Low Balance Accounts**
 - Count how many accounts have more than a threshold balance (e.g., Rs100,000).
 - Count accounts with zero balance.
6. **Average Balance**
 - Use total balance and total accounts to compute the average.
 - Print accounts above and below average.
