1. How did you approach the problem?

To address the problem, We developed a "Banking Management System" with key classes:

- USER
- USER CLIENT
- BANKING EMPLOYEE
- TRANSACTION
- CARD
- COMPANY CLIENT
- ACCOUNT TYPE (with specific subtypes: GOLD, BUSINESS, and BRONZE)

Step-by-Step Approach:

● Understanding the Requirements:

At the start of the project, we carefully analyzed the problem requirements. This involved identifying the key features the system needed, such as account creation, a login system, and the ability to handle multiple user roles (e.g., clients, employees, and companies).

● UML Diagram Creation:

We designed a "UML Diagram" to map out the relationships between the various classes. The diagram served as a blueprint, allowing us to understand how each class interacted with others. We began with a dummy class diagram and refined it based on the system's specific requirements.

FIG. UML DIAGRAM FOR BANKING MANAGEMENT SYSTEM

- **Identifying Key Functionalities:**

We pinpointed the core functionalities required for the system, such as:

- ❖ Account Creation: Enabling users to create accounts with different types.
- ❖ Login System: Implementing login functionality for three distinct roles (user client, banking employee, and company client).
- ❖ Transaction Handling: Managing transactions and linking them to specific accounts.

- **Data Management:**

To store and manage data, we used text files for simplicity and modularity. These files included:

- ❖ `transaction.txt` for storing transaction records.
- ❖ `companies.txt` for company-related information.
- ❖ `cards.txt` for card details.
- ❖ `users.txt` for user account data.
- ❖ `company\_employees.txt` for information about employees linked to company clients.

- **Implementation:**

With the requirements clear and the class structure defined, we began coding the system. We ensured that each class encapsulated its specific responsibilities and interacted with other classes as defined in the class diagram. For instance:

- ❖ The TRANSACTION class handled all transaction-related operations.
- ❖ The CARD class managed card generation and validation.
- ❖ The ACCOUNT TYPE subclasses (GOLD, BUSINESS, BRONZE) defined specific account-related behaviors.

- **Testing and Refinement:**

After the initial implementation, we tested the system to ensure all functionalities worked as expected. This included verifying the login system, data storage in the respective files, and the seamless interaction between the classes.

2. What problems did you face while connecting to an external database?

- Authentication and Authorization Failures: Incorrect credentials or insufficient user permissions can block access to the database.
- Improper Connection Strings: Errors in the connection string (e.g., incorrect host, port, or database name) can prevent successful database connections.
- Network Connectivity Issues: Firewall restrictions, unstable internet connections, or blocked ports can prevent the system from connecting to the external database.

- Database Schema Design Errors: Incorrect relationships or missing tables in the database schema can result in failures or data inconsistencies when querying the database.

3. What was your motivation behind your particular management system (also applies to students working on banking management systems)?

The development of the Banking Management System is driven by the goal of applying software development concepts in a practical and meaningful way. This project allows us to deepen our understanding of essential principles such as modularity, data handling, and error management, while also enhancing our skills in C++ programming. The system is designed to perform key banking operations like account registration, secure login, and transactions in a simple and efficient manner.

Since banking systems are an integral part of daily life, working on this project provides valuable insights into how these systems handle secure transactions, manage customer data, and solve real-world problems. It also challenges us to address critical aspects like data validation, error handling, and ensuring smooth performance for multiple users.

In addition, this project lays the groundwork for creating more advanced systems in the future, such as online banking platforms or mobile banking applications. It also opens opportunities to integrate modern technologies like artificial intelligence for fraud detection and blockchain for enhanced security. Overall, this project demonstrates our ability to design and implement a functional system while showcasing our understanding of object-oriented programming, database management, and problem-solving—key skills that are crucial in software development.

4. How would you scale your system in the future?

While the current system is designed to meet the basic needs of managing user and company accounts, there are several ways the system can be scaled in the future to accommodate growth and enhance its functionality.

- **Web and Mobile Application**

We would develop a web or mobile application to allow users to access their accounts and perform transactions from anywhere. The app would offer a more intuitive and user-friendly interface, supporting features such as:

- ❖ Real-time account balance updates.
- ❖ Push notifications for account activities.
- ❖ Simplified access to transaction histories.

- **Security Enhancements**

The security of the system can be strengthened by integrating multi-factor authentication (MFA) for both users and banking employees. Additionally, encrypting sensitive account information, such as PINs and transaction details, would further protect user data.

- **Automated Loan System**

In the future, we would automate the loan approval process for company clients, incorporating predefined criteria like company size, financial history, and transaction volumes. This would streamline loan management and reduce administrative overhead.

- **Handling Multiple Branches**

To scale the system for larger banks with multiple branches, we would design a distributed architecture. This would allow each branch to manage its users and transactions while syncing with a central database to ensure data consistency.

- **Advanced Transaction Features**

Future updates could include the ability to process complex transactions such as international transfers, recurring payments, and detailed spending reports for individual and company clients.
